

Row level security

We can set row level security in our database so that regardless of what application you are coming from, the database will follow the protocol set in the database for row level security

What is row level security?

- We see row level security everywhere, for example on canvas we don't get to see everyone's grades, only our grades. Why? Because somewhere (ideally set in the database) we have row level security which only allows us to retrieve data from the tables that we are given access to that correspond to us (say a studentID)
- This is important because we don't want everyone to just be able to see everyone else's shit
